Project Title	O
How Do Nature's Elements Affect a Solar Panel's Power Production?	
110 W 20 T (actuary & Exemients Timeer a South Tumer & Tower T Controlled)	
Objectives/Goals Abstract	
The objective of our project is to examine how nature's elements, namely, the p	anel's angle to the sun,
shade, wind, rain, temperature, and dust will affect a solar panel's power product	tion, for the purposes of
determining the most ideal natural conditions in which a solar panel will be mo	st efficient.
Methods/Materials	$\checkmark$
Using a multi-meter, we measured a monocrystalline solar panels voltage and determine it's power production under various elements of nature. We first esta of the solar panel to the sun and measured how changing the angle of the panel Using the optimal angle as a constant for the rest of the project, we then teled to	urhperage output to
determine it's power production under various elements of nature. We first esta	Iblished the optimal angle
Using the optimal angle as a constant for the rest of the project, we then tered to	the panel under shade
conditions and various wind speed conditions using a leaf blower and an anemo	ometer for wind speed. In
addition, we tested the panel under rain conditions using a sprinkler and local ra	ain chart information to
estimate a typical rain event. We also tested the panel ander cold temperatures	by lowering the panel's
surface temperature with ice. Finally, we measured boy dust would alter the po	wer output of the panel.
Results	
From the data gathered, we found that the greatest change to the power output of determined by the amount of direct sunlight that was able to his the panel. Then	of a solar panel was
determined by the amount of direct sunlight that was able to have the panel. There	re was a drop off of power
production in our sunny day trials, from an average of 94.5 watts to only 3.5 watts, when the panel was in	
full shade. The other greatest change was the to the angle. When the panel was angled 40 degrees away from the sun, it caused the average to drop from 87.9 watts to 59.6 watts. Wind and rain had very little or	
from the sun, it caused the average to drop from 87.9 watts to 59.6 watts. Wind and rain had very little or no affect on the power production, while dust only created an average change of 2.5 watts. Contrary to our hypothesis, a lower temperature actually increased the panel's efficiency by an average of 19.9 watts	
our hypothesis, a lower temperature actually increased the panel's efficiency by	an average of 19.9 watts
when cooled down by about 68 degrees	
Conclusions/Discussion	
To provide the most production from a monocrystalline solar panel, the ideal co	onditions would be to keep
it away from shade, in direct spalight, and at a optimal angle to the sun if poss clean and dust free would be preferred, but his does not change the output that	ible. Keeping the panel
clean and dust free would be prefered, but this does not change the output that	drastically. Wind and rain
had little to no affect. If there is a way to keep the temperature of the panel coofull sunlight, overall power production would be increased.	n, wille still maintaining
Tun sunnight, overall power production would be increased.	
Summary Statement	
We examined how partire's elements affected a solar panel's power production.
