The Neural Limitations of Small Invertebrates Image: Note of the i	Name(s)	Project Number	
Project Title The Neural Limitations of Small Invertebrates Objectives/Goals According to scientific research, the only animals capable of feeling pain are there that can feel fear, anxiety, distress and terror, similar to what humans feel when we receive provides structli. Contrary to popular belief, new research implies that it is possible that certain increptors can recei anxiety. The purpose of this experiment was to observe species of invertebrate that plate there under extensive stimuli to see if they exhibit anxious behavior. Methods/Material8 Brine shrimp was selected for this experiment, an invertebrate that plate there under extensive stimuli to see if they exhibit anxious behavior. Methods/Material8 Brine shrimp were first placed in a container that was half dark and bat light. Electrical shocks were used as the stress-inducing stimuli for the purpor of reating maxious environment. The brine shrimp were first placed in a container that was half dark and bat light. After the unvertebrate they received mild electrical shocks. After, they were placed back into the unit introductainer where they received to see if there was a difference in their behavior. Result8 Naturally, brine shrimp are more attracted to light rares the tarker areas. This was observed when the brine shrimp were placed in the container that was half dark and half light. After the brine shrimp were exposed to stress-inducing stimuli in formor theories al stocks, their behavior in the half dark container changed slightly. On average, mere brine shrim preferred the darker side of the container after experiencing the electrical shocks were observed to them. Conclusions/Discussion Through experimentation, it were browered that they approve to the stress-inducing stimuli, more brine shrimp preferred to stay in the section bar was been to express anxiety, may in fact posses the ability to exhibit the common signs of anxefty of depress. Objectives/Goals Abstract Ongenity of scientific research, the only animals capable of feeling pain at three thit can feel fear, anxiety, distress and terror, similar to what humans feel when we receive poxicols simuli. Contrary to purpose of this experiment was to observe species of invertebrate in place three under extensive stimuli to see if they exhibit anxicous behavior. Mindex/Materials Brine shrimp was selected for this experiment, an invertebrate that it no math attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purpose of treatingthm anxious environment. The brine shrimp were first placed in a container that was half dark and half and their natural behavior in the container was observed. The shrimp were then moy of the a separate container where they received mild electrical shocks. After, they were placed back into the attract of the two were observed to see if there was a difference in their behavior. Mutually brine shrimp are more attracted to light areas, thus darker areas. This was observed when the brine shrimp were placed in the container that was half dark and half light. After the brine shrimp were exposed to stress-inducing stimuli in the form of becincal shocks, their behavior in the half dark container changed slightly. On average, mey brine shrimp were then observed the darker side of the container after experiencing the electrical shock than ther exposure to the stress-inducing stimuli, more brine shrimp were then the preveation of the vary of a start the two places the ability to express anxiety. The summary of the arest that the intervention in the section that was half dark and the intervention in the half dark container that was half dark and high light. After the brine shrimp were exposed to stress-inducing stimuli in the form of the contain the stress inducing stimuli in t	Project Title		
Objectives/Goals According to scientific research, the only animals capable of feeling pain are three the can feel fear, anxiety, distress and terror, similar to what humans feel when we receive noxious simuli. Contrary to popular belief, new research implies that it is possible that certain increptores can feel anxiety. The purpose of this experiment was to observe species of invertebrates and place these under extensive stimuli to see if they exhibit anxious behavior. Methods/Materials Brine shrimp was selected for this experiment, an invertebrate that it normally attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purposed retainant anxious environment. The brine shrimp were first placed in a container that was half dark at hubUght, and their natural behavior in the container was observed. The shrimp were them on the parate container where they received mild electrical shocks. After, they were placed back into the halt tark container where they received mild electrical shocks. After, they were placed back into the halt dark container where they were observed to to see if there was a difference in their behavior. Results Maturally, brine shrimp are more attracted to lightr area. Thus there there areas. This was observed when the brine shrimp were placed in the container that van half dark on half light. After the brine shrimp were exposed to stress-inducing stimuli in the form there here veroposed to them. Conclusions/Discussion Through experimentation, it was dury or brine skrime preferred the darker side of the container after experiencing the electrical shocks than before here were exposed to them. Conclusions/Discussion Through experimentation, it was dury or brine stress inducing stimuli, more brine shrimp preferred to stay in the section half was dark. This suggests that brine shrimp, which were originally believed to have too simple a neural varient to experse anxiety, may in fact possess the ability to exhibit the common signs of anxiet	The Neural Limitations of Small Invertebrates		
 Objectives/Goals According to scientific research, the only animals capable of feeling pain are three the can feel fear, anxiety, distress and terror, similar to what humans feel when we receive noxious simuli. Contrary to popular belief, new research implies that it is possible that certain increptines can feel anxiety. The purpose of this experiment was to observe species of invertebrates and place these under extensive stimuli to see if they exhibit anxious behavior. Methods/Materials Brine shrimp was selected for this experiment, an invertebrate that it normally attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purpose of reating an anxious environment. The brine shrimp were first placed in a container that was half dark and hub light, and their natural behavior in the container was observed. The shrimp were then more that a shalf dark and hub light, and their natural behavior in the container was observed. The shrimp were placed back into the half dark container where they received mild electrical shocks. After, they were placed back into the half dark container where they were observed to see if there was a difference in their behavior. Results Naturally, brine shrimp are more attracted to light area. This data observed when the brine shrimp were exposed to stress-inducing stimuli in the form of lice scical slocks, their behavior in the half dark container changed slightly. On average, more brine shrimp referred the darker side of the container after experiencing the electrical shock, than before here were possed to them. Conclusions/Discussion Through experimentation, it was during the type and the supersess inducing stimuli, more brine shrimp preferred to stay in the section half was dark if this suggests that brine shrimp, which were originally believed to have too simple a neural were they exposed to them.  Objectives/Goals According to scientific research, the only animals capable of feeling pain and three thit can feel fear, anxiety, distress and terror, similar to what humans feel when we receive noxious simuli. Contrary to popular belief, new research implies that it is possible that certain increptines can feel anxiety. The purpose of this experiment was to observe species of invertebrates and place dissounder extensive stimuli to see if they exhibit anxious behavior. Methods/Materials Brine shrimp was selected for this experiment, an invertebrate that it normally attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purpose of reating an anxious environment. The brine shrimp were first placed in a container that was half dark and hub that, and their natural behavior in the container was observed. The shrimp were then more than a container where they received mild electrical shocks. After, they were placed back, into the half dark container where they received mild electrical shocks. After, they were placed back, into the half dark container where they received mild electrical shocks. After, they were placed back, into the half dark container where they were observed to see if there was a difference in their behavior. Results Naturally, brine shrimp are more attracted to light area. Thus there there was a observed when the brine shrimp were feared back into the back dark container changed slightly. On average, more brine shrimp referred the darker side of the container after experiencing the electrical shock, than before here were boyoes to them. Conclusions/Discussion Through experimentation, it was observed then they expense to the stress-inducing stimuli, more brine shrimp preferred to stay in the section data as dark? This suggests that brine shrimp, which were originally believed to have too simple a neural were they exposed to them. Summary Stutement Summary Stutement Methods and any day of the a	Abstract		
 anxiety, distress and terror, similar to what humans feel when we receive poxicles stimuli. Contrary to popular belief, new research implies that it is possible that certain incredentes can reel anxiety. The purpose of this experiment was to observe species of invertebrate the plate. The methods are extensive stimuli to see if they exhibit anxious behavior. Method/Materials Brine shrimp was selected for this experiment, an invertebrate that it normally attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purpose of reating. An attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purpose of reating. An attracted to light. Electrical shocks were used as the stress-inducing stimuli afor the purpose of reating. An attracted to light electrical shocks. After, they were placed back into the half dark that there ontainer was observed. The shrimp were then moved that a separate container where they received mild electrical shocks. After, they were placed back into the half dark that there was a difference in their behavior. Results Naturally, brine shrimp are more attracted to light areas than darker areas. This was observed when the brine shrimp were placed in the container that was half dark and half light. After the brine shrimp were exposed to stress-inducing stimuli in the form of the criccal stocks, their behavior in the half dark container changed slightly. On average, more brine strimp. Preferred the darker side of the container after experiencing the electrical shock that before hey were vaposed to them. Conclusions/Discussion Through experimentation, it wis discovered that ster exposure to the stress-inducing stimuli, more brine shrimp preferred to say in the section that as dard. This suggests that brine shrimp, which were originally believed to have too simple a neural vapor to express anxiety, may in fact possess the ability to exhibit anxiety and depression, which implies the	Objectives/Goals ()		
Description of the experiment was to observe species of invertebrate and place the under extensive stimuli to see if they exhibit anxious behavior. Methods/Materials Brine shrimp was selected for this experiment, an invertebrate that it normally attracted to light. Electrical shocks were used as the stress-inducing stimuli for the purpose of sreating an anxious environment. The brine shrimp were first placed in a container that was half dark and half light, and their natural behavior in the container was observed. The shrimp were then more time a separate container where they received mild electrical shocks. After, they were placed back in the half dark container where they received mild electrical shocks. After, they were placed back in the half dark container where they were observed to see if there was a difference in their behavior. Results Naturally, brine shrimp are more attracted to light rarea, they darker areas. This was observed when the brine shrimp were placed in the container that was half dark and half light. After the brine shrimp were exposed to stress-inducing stimuli in the formore between were were backs, their behavior in the half dark container changed slightly. On average, more brine shrimp breferred the darker side of the container after experimenting the electrical shock than before they were were posed to them. Conclusions/Discussion Through experimentation, it was discovered that here exposure to the stress-inducing stimuli, more brine shrimp preferred to stay in the section that they adard. This suggests that brine shrimp, which were originally believed to have too simple a neural volume to express anxiety, may in fact possess the ability to exhibit the common signs of anxiety of depression. If further research is conducted in this area and the results are similar, the implications have of the a restructuring of the way in which invertebrates are regarded. Functional production in the ability to exhibit anxiety and depression, which	According to scientific research, the only animals capable of feeling pain are	those that can feel fear,
