Project Title	0
The Effect of the Molality of Salts on Freezing Points of Water	
	\sim
6	$\sum \sum$
Objectives/Goals Abstract	
I try to find out how the affect of changing molality of salts, effects the freezing	point of water. This is
relevant in that, today America spends millions on deicing roadways and in my	experiment i try to find an
easier, cheaper way to get the same result. Methods/Materials	
Materials: Plastic Test tubes and rack. Beakers (50 mL) A Scale (plus or minuted)	50.01 g). Lab Ouest and
Materials: Plastic Test tubes and rack, Beakers (50 mL). A Scale (plus or minus Thermometer attachment (plus or minus 0.1 degree Celsius), Standard frish wa	ter ice, A cooler, Salt
(NaCl food grade), Salt NaCl lab grade, Salt MgCl2 lab grade, Stir stick &# 20	03;
For my Procedure I took the salts and measured out amounts out that followed a	as 0.2 mobality change to
10g of water that I previously measured out. I did this three times, for both salts 0.5 to 1.9 mol/kg. For each I observed the solution unit frozen and then I record	s, varying molality from
0.5 to 1.9 mol/kg. For each I observed the solution unit frozen and then I record	ded the results.
Results	by the Magnacium
My end results showed me that, in the end the Socium Chloride was out shown by the Magnesium Chloride, as the MgCl was more effective in all of the tests at lowering the freezing points of the solution.	
Conclusions/Discussion	
After reviewing my results I can determine that they yielded he same result as other tests with freezing	
points and salts. As the molality rose the freezing point of the solution traveled in a downward trend. Therefore, these results fall inline with what is clready known and show no drastic differences or abnormalities than what was previously known in this specific area of chemistry. In general the Magnesium chloride out preformed the Sodium chloride but economically the sodium chloride proves still	
abnormalities than what was previously knows in this specific area of chemistry. In general the	
Magnesium chloride out preformed the Sodium chloride but economically the sodium chloride proves still	
the more worth it. As all three trial graphs show, as the molality of the solutions increase there is a downwards trend (lower freezing point) for the solution. This is likely due to the higher amount of ions	
downwards trend (lower freezing point) for the solution. This is likely due to the higher amount of ions	
present in the water preventing the water molecules from freezing. There is also an obvious trend between Magnesium Chloride and Sodium Ovorida. Magnesium Chloride clearly has lower freezing points at	
all molalities on all trials.​:	
Summary Statement	
In my project I vary amounts of salts and test to see their effect on the freezing point of water.	
Help Received	
Dr. Sidhu, teacher, provided the space for me to do the project, other than that i had no help.
