

**CALIFORNIA SCIENCE & ENGINEERING FAIR  
2018 PROJECT SUMMARY**

<b>Name(s)</b> <b>Aadi Duggal; Rishab Lenka; Adrian Liu</b>	<b>Project Number</b> <b>S0309</b>
<b>Project Title</b> <b>Investigating Fluid Patterns to Determine the Efficacy of an Airfoil</b>	
<p style="text-align: center;"><b>Abstract</b></p> <p><b>Objectives/Goals</b> The focus of this research is on the optimization of wind power and airflow, and the experimental derivation of drag and lift on energy savings.</p> <p><b>Methods/Materials</b> 3D printed airfoils were created using the NACA 0012 airfoil and modifying the control group to biomimetically emulate natural designs such as Humpback Whale Tubercles as well. The force of drag was experimentally determined by measuring the amount the airfoil was pushed via a spring scale. The force of lift was experimentally determined by measuring the change in weight before and after the airflow over the airfoils.</p> <p><b>Results</b> The results had shown a consistently lower drag force and consistently higher lift force in the experimental airfoil, with a delayed stall and flow separation as per the CFD (Computer Fluid Dynamics) simulations.</p> <p><b>Conclusions/Discussion</b> Real world implications include reductions in the fuel economy of airplanes, windmills, next-generation cars, boats and other objects that move through fluids such as air or water.</p>	
<b>Summary Statement</b> The aerodynamic efficacy of different airfoils, inspired from real world species, was determined by measuring the different aerodynamic forces on the airfoils, while a CFD simulation was used to verify our results and explain the mechanism.	
<b>Help Received</b> David Uken helped us in 3D printing our airfoil
